

# SLIDING INTO BDOS

## PART I

### SLIDING INTO BDOS

#### THE SMOOTH AND EASY WAY

by: Michael J. Karas

Simi Valley, CA 93065

What is this thing everybody is talking about called BDOS? This series will attempt to answer this question in some detail but first we need a little basis to understand WHY in the first place. Digital Research CP/M is an operating system for smaller type micro processor computer systems that is designed to remove much of the normal computer operation drudgery experienced by the computer operator. The operating system software embodies a "system philosophy" that structures and generalizes upon the operating environment of a piece of electronics hardware. The environment presented actually allows that piece of quiet, transistorized machinery to be used at a much higher level. The full impact of what this operating system provides to a computer is most probably felt by the typical micro computer hacker that worked the hard way to get a computer system up and running. While building, debugging, and integrating the pieces, the computer was just a whole bunch of parts interfaced together in an organized manner. However, when the thing is finally a "computer" how does it get used. The low level process of poking data into memory from a frontpanel or even filling, dumping, or block moving memory data with an EPROM based "monitor program" hardly makes this computer "useful". The process of putting on disks and bringing up CP/M lights the torch for computer usability. In this case the hacker experiences an elated feeling now "NOW I CAN DO SOMETHING!"

Buried inside of the total operating system presentation is the concept of generalization brought up in the previous paragraph. One of the major requirements in order to make a computer useful is that there has to be applications software that performs the jobs intended for the computer. Jobs like accounting, word processing, spread sheet data analysis, or inventory control. Unfortunately the process of producing applications software is very, very expensive. A good package may take anywhere from one to ten man years of development effort to

make. If the process of making an applications package had to be custom taylored to a specific hardware environment, then there would not be affordable software available for use upon a given XYZ computer. Generalization in the operation of a computer environment solves this problem however. With the understanding that at a certain level "all microprocessor computer systems are alike" it is possible, with minimum constraints, to define a set of logical type operations that make a computer useful.

This logical set of operations, for the Digital Research CP/M operating system, is defined within the BDOS portion of the operating system. Here in about 3 1/2 K bytes of tightly written assembly language is the "generalization converter" that takes I/O requests for hardware independant applications programs and turns them into a lower level set of simplistic hardware oriented functions that are then processed through the BIOS. This conversion process is beneficial in the light that CP/M Ver 2.2 can be setup to run on a typical brand XYZ computer for about one half of the effort needed to convert even one of the simplest application packages had that application been written in a hardware dependant manner. Conclusion; software developers can make better, more sophisticated applications available for lower cost and computer users find a competitive software market place where there are many times multiple packages available that perform similar functions.

The thrust of this presentation is to show the prospective applications programmer how to use most of the generalized set of "BDOS System Calls" within Digital Researches CP/M Ver 2.2. The presentation scheme will be to describe all of the functions and use simple examples. The reader is assumed to be modistly familiar with 8080 Assembly Language Programming as all of the examples will be given in machine language. Likewise, in this environment it is assumed by default that the prospective programmer is planning to code in assembly language. If a CP/M compatible high level language is used for programming, such as Digital Research PL/I-80 or Microsoft BASIC-80, then of course the program interface at the "System Call" level becomes transparent to the programmer. Run time subroutines make the high level coded application get converted through yet another step. (One major reason applications code in a high level language runs slower than the equivalent function written in assembly language).

## SUMMARY OF CP/M SYSTEM CALLS

The set of system or "BDOS" I/O entry points available to the CP/M programmer is complete yet simple. The primary beauty of the CP/M system is this small world of completeness. Many programmers familair with other operating systems complain that the CP/M system is weak, unflexible, and incomplete. However, in

a microprocessor type computer world, the generalization level defined for the CP/M system allows 85% of all microprocessor type application jobs to be programmed with relative ease. Also, in my opinion, 8-bit microprocessor hardware is easily capable of performing about 90 percent of the typical tasks targeted for microcomputers. So what is this set of functions? The chart of Figure 1 summarizes, in function number order, all of the system operations specific to CP/M Version 2.2 that will be covered in this presentation. In the subsequent sections that follow the functions will be grouped into categories so that related operations may become familiar with reference to one another.

FIGURE 1. DETAILED SUMMARY OF CP/M 2.2 SYSTEM CALLS

Function Number	Entry Value to BDOS Passed in (DE) or (E) regs	Return Value from BDOS Passed in (HL) or (A) register
DEC HEX	Function	
0 00	System Reset	****
1 01	Console Input	(A)=character
2 02	Console Output	(E)=character
3 03	Reader Input	****
4 04	Punch Output	(A)=character
5 05	Printer Output	(E)=character
6 06	Direct Console I/O	****
		(E)=0FFH is input
		(A)=character
		(E)=chr is output
7 07	Get IOBYTE	****
8 08	Set IOBYTE	(A)=IOBYTE
9 09	Display Console String	****
10 0A	Input Console String	(DE)=string addr
11 0B	Get Console Status	****
		(A)=# chr input
		****
		(A)=000H idle
		(A)=0FFH ready
12 0C	Get CP/M Version Number	****
13 0D	Reset Disk Subsystem	(HL)=Version #
14 0E	Select Disk Drive	****
15 0F	Open a File	(E)=disk number
16 10	Close a File	****
17 11	Search for File	(DE)=FCB address
18 12	Search for Next	(A)=dir code
19 13	Delete File	****
20 14	Read next Record	(DE)=FCB address
21 15	Write next Record	(A)=dir code
22 16	Create New File	(DE)=FCB address
23 17	Rename File	(A)=error code
24 18	Get Login Vector	(DE)=FCB address
25 19	Get Logged Disk Number	(A)=dir code
26 1A	Set R/W Data Buff Addr	(DE)=FCB address
27 1B	Get Allocation Vector	(A)=error code
		(DE)=buffer addr
		****
		(HL)=alloc vector
		address
28 1C	Write Protect Disk	****
		(E)=disk number

29	1D	Get Read Only Vector		****	(HL)=R/O vector	
30	1E	Set File Attributes		(DE)=FCB address	(A)=dir code	
31	1F	Get Addr of Disk Parms		****	(HL)=parm addr	
32	20	Get/Set User Select		(E)=0FFH get	(A)=current user	
33	21	Read Random Record		(DE)=long FCB adr	(A)=error code	
34	22	Write Random Record		(DE)=long FCB adr	(A)=error code	
35	23	Get Size of File		(DE)=long FCB adr	(r0-2=rec cnt)	
36	24	Set Random Record Num		(DE)=long FCB adr	(r0-2=rec numb)	
37	25	Reset Drive		(DE)=drive vector	****	
38	26	Not used				
39	27	Not used				
40	28	Write Random with		(DE)=long FCB adr	(A)=error code	

-----

The technical means required to "use" or interface to the CP/M system for each function contains a certain common structure that will be discussed here. The base memory page of a CP/M system memory map includes, at a specific memory address, a JUMP instruction to the CP/M BDOS entry point. For most CP/M systems this is address 00005H. To accomplish BDOS I/O the number of the function is placed into the (C) register. If the parameter requires input parameters, then they are passed in the (DE) register pair or the individual (E) register depending upon whether the parameter is a word or byte value. Result information returned by some functions is sent back to the users program in either the (A) register or the (HL) register pair depending upon if the value is a byte or word. The following simple program segment demonstrates the scheme used to output the 26 characters A-Z to the console screen through the use of function number 2.

```

BDOS      EQU      0005H          ;SYSTEM ENTRY
CONOUT    EQU      2             ;OUTPUT FUNCTION

          ORG      0100H          ;TPA BASE
          MVI     B,26           ;PRINT 26 COUNTER
          MVI     C,'A'         ;START WITH 'A'

;
LOOP:
          PUSH    B              ;SAVE COUNTER & LETTER
          MOV     E,C           ;LETTER TO (E) FOR OUTPUT
          MVI     C,CONOUT      ;BDOS FUNC TO (C)
          CALL   BDOS          ;GO GO OUTPUT
          POP     B
          INR     C              ;SEQUENCE TO NEXT CHAR
          DCR     B              ;DECREASE CHR COUNTER
          JNZ    LOOP          ;MORE TO DO IF NOT TO ZERO
          RET                    ;IMMEDIATE CCP RETURN
    
```

SYSTEM CALLS FOR OPERATOR CONSOLE INPUT AND OUTPUT

Intrinsic to the operation of any computer system, especially of the CP/M gender, is the operator console. The device provides the human interface to the machine and as such the BDOS includes a generalized set of operator communication functions to perform I/O with the console device. The various options available will each be presented with a brief example.

#### INPUT FROM CONSOLE KEYBOARD: Function 1.

This function waits for and reads in a character from the console device keyboard. The operator typed character is echoed automatically back to the console display if the character is an ASCII printable character (020H to 07EH) or it is a carriage return, line feed, back space, or tab. Note that the BDOS automatically expands tabs to columns of eight characters. Upon outputting the character for the echo, a check is made for console start/stop, CTL-S, and if so the console input routine does not return to the users program until another arbitrary key is depressed.

#### ;CONSOLE INPUT EXAMPLE

```

;
CONIN    EQU        001H           ;FUNC # 1
BDOS     EQU        0005H         ;SYSTEM ENTRY

        ORG        0100H         ;START
        MVI        C,CONIN       ;FUNCTION
        CALL       BDOS          ;GO GET CHARACTER
        STA        INCHAR        ;SAVE FOR WHATEVER REASON
        RET                ;IMMEDIATE CCP RETURN
;
INCHAR:
        DS         1             ;PLACE TO STORE INPUT CHAR
;
        END

```

#### OUTPUT TO CONSOLE DISPLAY: Function 2.

The ASCII character in the (E) register is sent to the console display device. The output may be any byte value but many times the hardware driver BIOS routines automatically strip off the upper bit of the byte. Upon output the printer echo flag within BDOS is checked (CTL-P) and if set the character is also sent to the printer peripheral device. Note that the BDOS automatically expands output tabs to columns of eight characters. Upon outputting the character a check is made for input of console start/stop, CTL-S, and if so the console output routine does not return to the users program until another arbitrary key is depressed.

```

;CONSOLE OUTPUT EXAMPLE
;
CONOUT    EQU        002H            ;FUNC # 2
BDOS      EQU        0005H          ;SYSTEM ENTRY

        ORG         0100H          ;START
        LDA         OUTCHAR        ;GET CHARACTER TO OUTPUT
        MOV         E,A
        MVI         C,CONOUT       ;FUNCTION
        CALL        BDOS           ;GO SEND CHARACTER
        RET          ;IMMEDIATE CCP RETURN

;
OUTCHAR:
        DB         'X'            ;PLACE TO GET OUTPUT CHAR
;
        END

```

DIRECT USER INTERFACE TO CONSOLE: Function 6.

Some programming applications require that the BDOS not monitor the input/output character stream as is done with functions 1 & 2. To allow for these functions the direct I/O function is supported. The following example shows how it is used to input values and echo them until an input control-Z character is typed.

```

;DIRECT CONSOLE I/O EXAMPLE
;
DIRCIO    EQU        006H            ;FUNCTION NUMBER
BDOS      EQU        0005H          ;SYSTEM ENTRY POINT
CTLZ      EQU        'Z'-040H       ;ASCII CTL-Z CHARACTER
INPUT     EQU        0FFH           ;DIRECT INPUT FLAG

        ORG         0100H          ;CONSOLE INPUT
;
LOOP:
        MVI         E,INPUT        ;SET FOR INPUT
        MVI         C,DIRCIO       ;FUNCTION
        CALL        BDOS           ;GET INPUT OR STATUS
        ORA         A              ;IF (A)=0 NO CHAR WAS READY
        JZ          LOOP           ;CONTINUE TO WAIT FOR INPUT
        CPI         CTLZ           ;IF INPUT WAS CTL Z THEN END
        RZ          ;CCP RETURN ON END
        MOV         E,A            ;CHARACTER TO (E) FOR OUTPUT
        MVI         C,DIRCIO       ;SAME FUNCTION NUMBER AGAIN
        CALL        BDOS           ;GO OUTPUT IT
        JMP         LOOP           ;NEXT CHARACTER INPUT LOOP
;
        END

```

## PRINTING STRINGS OF CHARACTERS TO THE CONSOLE: Function 9.

Message string sequences of characters to be sent to the console are quite common in applications programming. Typical uses may be for user prompt messages, program sign-on messages etc. The BDOS provides a convenient mechanism to allow the programmer to output a whole string of characters rather than having to loop with single character outputs. The string is intended to be stored in consecutive memory locations and end with the ASCII '\$' character. The (DE) registers are used to point to the start of the string. The '\$' signals the end of the string to display and is not sent to the console. The output bytes may be any 8-bit value but many times the hardware driver BIOS routines automatically strip off the upper bit of the byte. Upon output of each character the printer echo flag within BDOS is checked (CTL-P) and if set the character is also sent to the printer peripheral device. Note that the BDOS automatically expands output tabs to columns of eight characters. Upon outputting each character a check is made for input of console start/stop, CTL-S, and if so the console string output routine does not return to the users program until another arbitrary key is depressed.

;CONSOLE STRING PRINT EXAMPLE

```

;
CONSTR    EQU        009H            ;FUNC # 9
BDOS      EQU        0005H          ;SYSTEM ENTRY
CR         EQU        0DH           ;ASCII CARRIAGE RETURN
LF         EQU        0AH           ;ASCII LINE FEED

          ORG        0100H          ;START
          LXI        D,MESSAGE      ;POINT AT STRING TO SEND
          MVI        C,CONSTR       ;FUNCTION
          CALL       BDOS           ;GO SEND STRING
          RET          ;IMMEDIATE CCP RETURN
;
MESSAGE:
          DB         CR,LF,'Hello Operator',CR,LF,'$'
;
          END

```

## READING A STRING OF CHARACTERS IN FROM KEYBOARD: Function 10.

The CP/M console command processor (CCP) assumed to be vary familiar to most CP/M system operators allows buffered command input with editing features. It turns out that this operation is a much needed function for getting in strings of text from the operator console. Use of this function allows standardization of the command input functions so that the operator can easily learn the editing key functions. It also removes the pain of writing the same function over and over again by the applications programmer. The read string command inputs the edited text to a

buffer pointerd to by the (DE) register pair. The caller specifies the maximum length desired and the BDOS returns the actual length of string entered if carriage return is entered prior to exceeding the maximum input length. The input length is returned in both the (A) register and as part of the buffer. Bytes in the string buffer past the end of the entered text are uninitialized. The example shown below gives an assembly language view point of the buffer structure and how to program an input function.

The editing functions supported are the following control and/or special characters:

rub/del	removes and echos the last entered char
ctl-C	initiates system reboot if first char
ctl-E	echos a CR & LF to console without putting them into buffer
ctl-H	(or back space key) back spaces one char removing last entered character
ctl-J	(or line feed key) terminates line input
ctl-M	(or carriage return) terminates input
ctl-R	retypes currently entered characters under current line
ctl-U	deletes all of currently entered data and restarts buffer input on new line
ctl-X	deletes all of currently entered data and restarts buffer input on same line

;CONSOLE INPUT BUFFER EXAMPLE

```

;
CONBUF EQU 00AH ;STRING INPUT FUNCTION
BDOS EQU 0005H ;SYSTEM ENTRY POINT
LENGTH EQU 32 ;DESIRED MAXIMUM CHARACTERS

ORG 0100H ;START POINT
LXI D,STRING ;POINT AT BUFFER AREA
MVI C,CONBUF ;FUNCTION NUMBER
CALL BDOS ;GO GET STRING
RET ;RETURN TO CCP WITHOUT
;...DOING ANYTHING WITH DATA
;
;

```

;CONSOLE INPUT BUFFER LAYOUT

```

;
STRING:
DB LENGTH ;MAXIMUM DESIRED INPUT LENGTH
AMOUNT:
DS 1 ;BYTE WHERE BDOS RETURNS
;..ACTUAL BYTE COUNT
STRBF:
DS LENGTH ;RESERVED STORAGE FOR UP TO

```

```

; "LENGTH" NUMBER OF CHARACTERS
;
      END

```

DETERMINING IF THERE IS PENDING KEYBOARD INPUT: Function 11.

Some computer programs are designed to spend large amounts of time processing inside of the computer or manipulating data within disk files without stopping to ask the user if he/she desires to stop the processing sequence. Also it is many times desirable to have a "terminate" capability for application programs without waiting for the operator to answer a character input request. If the normal console input function is used the user computer is not resumed until a character is already input. The console input status check function may be used to poll the user keyboard to determine if a character input is pending. If no input is ready then the user program is immediately resumed with an indication of if there was a pending input. If a character is pending a 0FFH is returned in the (A) register. Otherwise a 000H value is returned. The following example illustrates the use of console status to terminate a normally endless loop that prints the same string over and over.

```

;CONSOLE STATUS USAGE EXAMPLE
;
CONSTAT EQU 00BH ;FUNC # 11
CONSTR EQU 009H ;PRINT STRING FUNCTION
BDOS EQU 0005H ;SYSTEM ENTRY
CR EQU 0DH ;ASCII CARRIAGE RETURN
LF EQU 0AH ;ASCII LINE FEED

      ORG 0100H ;START
LOOP:
      LXI D,MESSAGE ;POINT AT STRING TO SEND
      MVI C,CONSTR ;FUNCTION
      CALL BDOS ;GO SEND STRING
      MVI C,CONSTAT ;GET ABORT STATUS
      CALL BDOS
      ORA A ;CHECK STATUS
      JZ LOOP ;NO KEY SO CONTINUE LOOP
      RET ;IMMEDIATE CCP RETURN IF ABORT
;
MESSAGE:
      DB CR,LF,'Depress any Key to STOP','$'
;
      END

```

## AUXILLIARY PERIPHERAL CHARACTER INPUT AND OUTPUT FUNCTIONS

The generalized CP/M BDOS provides the capability for three character by character logical I/O devices to be attached to the computer system. This requirement stems from the fact that most computers are designed to interface to the real world in more ways than just a console device. The three devices are classified as:

a) A lister type device that is generally expected to be a printer of some sort. This classification is an output only device.

b) An input device supporting character input from a source other than the console. The device is specifcally an input type unit. CP/M jargon refers to this device as the "READER" for no particular reason.

c) A generalized character output only device used as a specific data destination other than the console or standard list device. Some computer systems use this device, often times referred to as the "PUNCH" device as a second printer output.

The three following examples illustrate the programming techniques used to talk to each of these three devices.

### ;LIST DEVICE OUTPUT EXAMPLE

```

;
LIST      EQU      005H      ;FUNC # 5
BDOS     EQU      0005H    ;SYSTEM ENTRY

        ORG      0100H      ;START
        LDA      LSTCHAR    ;GET CHARACTER TO OUTPUT
        MOV      E,A
        MVI      C,LIST     ;FUNCTION
        CALL     BDOS       ;GO SEND CHARACTER
        RET      ;IMMEDIATE CCP RETURN
;
LSTCHAR:
        DB      'L'        ;PLACE TO GET OUTPUT CHAR
;
        END

```

### ;READER DEVICE INPUT EXAMPLE

```

;
READER   EQU      003H      ;FUNC # 3
BDOS     EQU      0005H    ;SYSTEM ENTRY

        ORG      0100H      ;START

```

```

        MVI      C,READER      ;FUNCTION
        CALL    BDOS          ;GO GET CHARACTER
        STA     RDRCHR        ;SAVE FOR WHATEVER REASON
        RET     ;IMMEDIATE CCP RETURN
;
RDRCHR:
        DS      1            ;PLACE TO STORE INPUT CHAR
;
        END

;PUNCH DEVICE OUTPUT EXAMPLE
;
PUNCH   EQU     004H        ;FUNC # 4
BDOS    EQU     0005H      ;SYSTEM ENTRY

        ORG     0100H      ;START
        LDA     PNCHCHR    ;GET CHARACTER TO OUTPUT
        MOV     E,A
        MVI     C,PUNCH    ;FUNCTION
        CALL    BDOS       ;GO SEND CHARACTER
        RET     ;IMMEDIATE CCP RETURN
;
PNCHCHR:
        DB     'P'        ;PLACE TO GET OUTPUT CHAR
;
        END

```

## SYSTEM CONTROL BDOS FUNCTIONS

This family of system calls supported by the CP/M BDOS are designed to allow the programmer a degree of flexibility in manipulating the operation of general CP/M environment. Each function here will generally be discussed individually due to the unique nature of each operation.

### SYSTEM RESET: Function 0.

The system reset function is designed to allow restart of the CP/M system command processor after a user application completes execution or is aborted. The system reset function is equivalent to a JMP to address 0000H or a CTL-C which forces a system WARM Reboot. The reboot operation de-activates all active drives except drive A: which is re-logged. Operation is extremely simple as:

```

RESET   EQU     000H        ;SYSTEM RESET FUNC

```

```
BDOS      EQU      0005H          ;SYSTEM ENTRY POINT

          ORG      0100H
          MVI      C,RESET
          JMP      BDOS          ;CALL ALSO PERMISSABLE
                                   ;EXCEPT THAT FUNCTION
                                   ;DOES NOT RETURN TO USER
                                   ;PROGRAM
```

GET AND SET IOBYTE: Functions 7 & 8.

The generalized CP/M operating system environment communicates via I/O to "logical" type devices. This means that the console, lister, "reader", and "punch" are just treated as a generic device classifications. The CP/M system allows for and supports, to a degree, the capability for the hardware to contain multiple physical devices (peripherals and/or real I/O devices) within each of the generic logical device classifications. The means to support the assignment of multiple physical devices to a given classification is done through the IOBYTE, normally stored at address 00003H of the base page of the CP/M memory. The BIOS hardware I/O software may thusly be written to easily know which one of two printers to talk to when the BDOS requires output to one of two printers. A "default standard" IOBYTE format has been adopted based upon an 8-bit microprocessor system convention developed by Intel Corp as follows:

		(lister)	(punch)	(reader)	(console)
Logical Devices =>		LST:	PUN:	RDR:	CON:
IOBYTE bits =>		7 6	5 4	3 2	1 0
-----					
Bit pattern					
dec	binary				
0	00	TTY:	TTY:	TTY:	TTY:
1	01	CRT:	PTP:	PTR:	CRT:
2	10	LPT:	UP1:	UR1:	BAT:
3	11	UL1:	UP2:	UR2:	UC1:

The designators in the table specify the "standard types of physical devices and are defined as follows:

- TTY: A teletype console with keyboard, hard copy display and possibly an integral tape reader/punch
- CRT: An interactive cathode ray type terminal with keyboard input and display screen
- BAT: A batch processor workstation with a card reader type input device and a hard copy display/output device
- UC1: A user defined alternate "console" unit
- LPT: Line printer
- UL1: A user defined list device

```

PTR: Paper Tape Reader
UR1: User defined "reader" character input device
UR2: User defined "reader" character input device
PTP: Paper Tape Punch
UP1: User defined "punch" character output device
UP2: User defined "punch" character output device

```

The BDOS support for the I/O device assignment is a standard mechanism to access the IOBYTE's current value and switch it to some other value. Suppose a CP/M computer had two printers connected as LST: and UL1:. If the applications program needs to switch printing output to another printer, the process could be handled as follows:

```

;GET AND SET IOBYTE EXAMPLE
;
SETIOB EQU 008H ;SET IOBYTE FUNCTION
GETIOB EQU 007H ;GET IOBYTE FUNCTION
BDOS EQU 00005H ;SYSTEM ENTRY POINT
LSTMASK EQU 11$00$00$00B ;IOBYTE MASK FOR LIST
;..DEVICE
LPT EQU 10$00$00$00B ;BIT VALUE FOR LPT #1
UL1 EQU 11$00$00$00B ;BIT VALUE FOR LPT #2

ORG 0100H ;PROGRAM START
MVI C,GETIOB ;GO GET CURRENT IOBYTE VAL
CALL BDOS
ANI (NOT LSTMASK) AND 0FFH ;KEEP ALL OTHER BITS
ORI UL1 AND LSTMASK ;SET IOBYTE FOR PRINTER #2
MOV E,A
MVI C,SETIOB ;FUNCTION TO RESET THE IOBYTE
CALL BDOS
RET ;IMMEDIATE CCP RETURN
;
END

```

GET CP/M VERSION NUMBER: Function 12.

Sometimes it is necessary for an applications program to "know" what version of CP/M the program is running under. Version 2.0 and above support a feature to tell the application program what the version number is. One reason is to permit version dependant functions such as random record file I/O to be used if it is supported by the version of CP/M being used. The system call to get the version number returns a two byte value split into two parts as follows:

```

if (H)=0 then this is a CP/M System
(H)=1 then this is an MP/M System
(L)=version number in hex

```

```

if (L)=00 then older than CP/M 2.0
(L)=20 then version CP/M 2.0
(L)=21 then version CP/M 2.1
(L)=22 then version CP/M 2.2

```

A program to read the CP/M version number is as follows:

```

;VERSION NUMBER EXAMPLE
;
GETVERS EQU 00CH ;FUNCTION 12
BDOS EQU 00005H ;SYSTEM ENTRY POINT

ORG 0100H ;PROGRAM START
MVI C,GETVERS ;FETCH VERSION NUMBER
CALL BDOS
MOV A,L ;SAVE CP/M VERSION NUMBER
STA CURVERS
RET ;BACK TO CCP

;
CURVERS:
DS 1 ;STORE THE VERSION NUM HERE
END

```

RESETTING THE CP/M DISK SYSTEM: Function 13.

The CP/M operating system contains features to control access to files upon the disk drives. A directory checksum scheme, beyond the scope of this presentation, permits the operating system to determine when a disk has been changed in a drive thus preventing the a wrong disk from being written upon. This is neat except that in many cases an applications program may require disk changes as functions are changed or new files are required. This system control function permits the application to force read/write status to be set for all drives, drive A: to be logged, and reset of the default disk record buffer address to its default value of 080H within the CP/M base page. The following program sequence shows how to reset the disk system.

```

;RESET DISK SYSTEM EXAMPLE
;
RESET EQU 0DH ;FUNCTION 13
BDOS EQU 0005H ;SYSTEM ENTRY POINT

ORG 0100H ;PROGRAM START
MVI C,RESET ;SET UP FUNCTION
CALL BDOS ;GO RESET THE DRIVES
RET ;BACK TO THE CCP

;
END

```

## GET AND SET OF CURRENT USER CODE: Function 32.

CP/M Version 2.2 permits the file system on a given drive to be partitioned into up to 15 individual directory areas so that usage areas can be setup. For instance, the system operator could put all assembly language development programs in one user area while having disk utility programs in another. The BDOS allows the application programmer to determine the currently logged user number and to modify it if necessary. The following example sets the current user number up by one. If the highest user number is currently logged then the user 0 area is selected.

```

;GET/SET USER EXAMPLE
;
GSUSR    EQU        020H        ;FUNCTION 20
GET      EQU        0FFH        ;GET FLAG
BDOS     EQU        0005H       ;SYSTEM ENTRY POINT

        ORG        0100H        ;START UP POINT
        MVI        E,SET        ;MAKE THIS A FETCH NUM RQST
        MVI        C,GSUSR
        CALL       BDOS        ;GET THE CURRENT USER #
        INR        A            ;BUMP RETURNED USER UP 1
        ANI        00FH        ;MASK TO MOD(15)
        MOV        E,A          ;MOVE FOR SET TO NEW USER
        MVI        C,GSUSR
        CALL       BDOS
        RET                    ;CCP GETS US BACK
;
        END

```

## SYSTEM FUNCTIONS THAT CONTROL THE DISKS

The data storage files for applications programs are stored upon the disk drives attached to the CP/M computer. The BDOS supports a number of functions that allow the state and selection status of the drives to be controlled.

## SELECT DISK: Function 14.

The simplest control function is to select the current disk with which to refer to as the logged or default disk. The function is equivalent to the console CCP command:

```

A>B:<cr>
B>

```

Which changed the currently logged disk to drive B:. A BDOS program to affect the same thing is given in the example program of the next section below. Drive numbers correspond to the

console displayed drive designators as follows:

A: = Drive # 0

B: = Drive # 1

\*\*\*

P: = Drive # 15

Once a drive has been selected it has its directory "activated" and is maintained in a logged in status until the next warm boot, cold boot, or disk reset BDOS function.

DETERMINE LOGGED DISK: Function 25.

An applications program can determine which disk drive is the currently logged or default drive through use of this function. The BDOS will return in the (A) register the number of the currently selected drive according to the table given above.

The program segment below shows a sequence of BDOS interface code that first determines if drive B: is selected, and if not then does a BDOS call to change it.

```
;SELECT AND POLL LOGGED DISK DRIVE EXAMPLE
;
SELECT    EQU        0EH          ;FUNCTION 14
ASKDRV    EQU        19H          ;FUNCTION 25
BDOS      EQU        0005H        ;SYSTEM ENTRY POINT

        ORG        0100H          ;PROG START
        MVI        C,ASKDRV       ;FIND OUT IF B: IS SELECTED
        CALL       BDOS
        CPI        'B'-'A'
        RZ                      ;DONT SELECT IF ALREADY
                                   ;..LOGGED
        MVI        E,'B'-'A'      ;SET TO LOG AND SELECT B:
        MVI        C,SELECT
        CALL       BDOS
        RET                      ;FINISHED WITH ANOTHER PROG
;
        END
```

DRIVE STATUS SET AND RESET: Functions 28 & 37.

Drive status may be individually controlled by these functions. Operation 28 allows a the currently selected drive to be write protected (set to read/only). The process is simply:

```

WPDSK    EQU        01CH
BDOS     EQU        0005H
          MVI        C,WPDSK          ;WRITE PROTECT DISK
          CALL       BDOS

```

The write protect status of a specific disk may be removed by function 37 which deactivates the directories of each drive specified at call time. Each drive by default then becomes read/write again but requires reactivation through reselection. The reset drive vector is a 16-bit value passed to the BDOS with a "1" bit in each bit position for a drive that requires resetting. The most significant bit of the 16 bit quantity corresponds to drive P: and the LSB to drive A:. The code sequence to reset drive B: would be:

```

RESDSK   EQU        025H
BDOS     EQU        0005H
          MVI        C,RESDSK        ;FUNCTION CODE
          LXI        D,0000$0000$0000$0010B ;DRIVE B: BIT SET
          CALL       BDOS

```

GET DRIVE LOGIN AND READ?ONLY VECTORS: Function 24 & 29.

The BDOS keeps track of all drives that have been selected since the last boot or disk reset functions. These drives are considered in an online status in that the system knows immediately what the space allocation map of the drive is and whether the drive is in read/only status or not. Function 24 allows the application program to determine what subset of the current drive complement are in this online logged status. The vector returned in the (HL) register pair is a bit map like above where a "1" bit means the drive is active. The most significant bit of the 16-bit number corresponds to drive P:. The code below fetches the vector and saves it in a local data area.

```

;LOGIN VECTOR EXAMPLE
;
LOGIN    EQU        018H          ;FUNCTION 24
BDOS    EQU        0005H        ;SYSTEM ENTRY POINT

          ORG        0100H
          MVI        C,LOGIN      ;FUNCTION
          CALL       BDOS
          SHLD       LOCL0G      ;SAVE VECTOR HERE
          RET          ;TO CCP
;
LOCL0G:
          DS         2
          END

```

In a similar manner the BDOS allows determination of which

drives are in the write protected read/only status. A "1" bit in the returned vector indicates read/only status for a specific drive. The code here shows how to fetch it.

```
;READ/ONLY VECTOR EXAMPLE
;
ROVEC    EQU    01DH          ;FUNCTION 29
BDOS     EQU    0005H        ;SYSTEM ENTRY POINT

        ORG    0100H
        MVI    C,ROVEC      ;FUNCTION
        CALL   BDOS
        SHLD   LOCROV       ;SAVE VECTOR HERE
        RET                ;TO CCP
;
LOCROV:
        DS    2
        END
```

GET ALLOCATION VECTOR AND DISK PARM POINTER: Function 27 & 31.

Two more miscellaneous disk drive interface functions are provided that permit several special types of functions to be performed. The first, function 27 returns an address in the (HL) registers that points to a bit string in memory that corresponds to the data block allocation map of the currently selected drive. The map contains one bits in each position where a block allocated, starting with the MSB of the first byte in the string. The length of the bit string depends upon the total capacity of the drive in allocatable blocks. Function 31 permits an application to determine the characteristics of the currently selected drive. The BDOS returns an address in the (HL) registers that points to a table of 33 bytes that describe the current drive. Data in the table includes such data as number of possible directory entries on the disk, number of allocatable blocks on the disk, and, indirectly, the size of each disk block. The program below is a comprehensive example of how these functions can be used to determine the remaining space left on a the selected drive. The program stores the available space of the drive specified in the first byte of the default FCB into memory location "KPDISK" and then exits to the CCP. The reader can adapt the code as desired.

```

The next part in this series will present the the CP/M file system as viewed from the BDOS interface aspect. The FILE CONTROL BLOCK (FCB) will be presented. In addition the procedures to prepare files for I/O and then the actual I/O procedures will be presented. The series will round out to a conclusion with a comprehensive programming example that presents a sequential file I/O set of subroutines that permit character by character I/O with a file to be done.

## PART II

SLIDING INTO BDOS (Part II)

WITH FILES MADE EASY

by:

Michael J. Karas  
2468 Hansen Court  
Simi Valley, CA 93065  
(805) 527-7922

Since I know that all devoted Life Lines readers have anxiously been waiting for this "second in a series" tutorial on using files with the CP/M BDOS, I will not go on a long time telling you why this thing about CP/M BDOS file interface is so important. Nor will I try to justify why the tutorial should be valuable. You wouldn't be reading here at this time if you had any inclination to find my work disinteresting. If you are new on the scene and have some questions about what this is all about I would like to direct your attention to the November 1982 issue of Life Lines where the first part of this tutorial series was presented. There the purpose of the BDOS and the general interface concepts were presented. The article went on to include a description of the physical device system calls and other miscellaneous system control type functions.

THIS TIME IT'S FILES

This month the tutorial continues with a description of the sequential file I/O system supported within the BDOS. The concepts of CP/M file storage are to be described along with appropriate CP/M directory structure definition as it relates to

the access of the files stored upon a CP/M disk. The FILE CONTROL BLOCK (FCB) will be described in terms of its functions as related to a file to be accessed upon a disk. I have also included a comprehensive programming example that allows a sequential file to be accessed character by character.

## HOW FILES ARE STORED UPON THE DISK

The CP/M operating system manages the available space on a disk by dividing the total available space up into a number of relatively small data block storage areas called "GROUPS". A group size is usually described as the minimum allocatable space that a file can occupy. What this means is that the operating system, in its disk space management scheme, lumps sets of the normal 128 byte logical records of a file together into these things called groups. The number of groups that may be contained on a disk depends upon the total file storage space of the disk in logical 128 byte records divided by the number of 128 byte logical records lumped together into a group. (A note to the less casual reader is that the number of groups on a disk is limited by design to 65K groups. Secondly a group is always an integral power of two number of 128 byte logical records with a minimum size of 8 records (1K byte). Group size is necessarily limited to 16K bytes due to the extent system described below).

As a file is stored upon a CP/M disk it consumes disk space in 128 byte logical records. Each time a group becomes filled with records the operating system allocates another group to the file. Hence the term "minimum allocatable size". If, as the file grows in size, the last allocated group assigned to a file is not completely filled the remaining space in the group is "burned" in that it is not usable by other files. The CP/M system keeps track of the group assignments made to the various files on a disk, the files names, and the total number of 128 byte logical records in each file through a stored directory. The first portion of the disk is reserved for the file directory. A fixed number of directory entries, determined by the system's BIOS design, are available, usually a number like 64, 128, or 256, depending upon the size of the disk.

Each file has a unique directory entry "set" that describes the file location upon the disk. A "set" of directory entries is specified because each entry is designed to "point to" or store the group allocation numbers for that file. Each directory entry has a number slots where group numbers can be stored. The system design allows each directory entry to specify the storage for 16K bytes of storage space. For files larger than 16K bytes a separate directory entry is used for each 16k bytes (or remainder portion thereof). Each such piece of a file is referred to as an "EXTENT" of the file. The directory entry "set" for a file

contains a byte in each extent directory entry that stores the extent number of the file. Extent numbers start with 0 and may increase to a theoretical limit of 255 or the size of the disk in 16K byte pieces, whichever is smaller.

The chart below describes the functions of all bytes in a typical directory entry. Each entry is 32 bytes long and they are packed four to a logical sector with the number of logical sectors filled up with directory entries limited to the predetermined number of directory entries divided by four.

Figure 1. DISK DIRECTORY ENTRY DEFINITION

byte 00	byte 01	byte 02	byte 03	byte 04	byte 05	byte 06	byte 07
+-----+-----+-----+-----+-----+-----+-----+-----+							
Active

Char						Extent	
+-----+-----+-----+-----+-----+-----+-----+-----+							
byte 16	byte 17	byte 18	byte 19	byte 20	byte 21	byte 22	byte 23
+-----+-----+-----+-----+-----+-----+-----+-----+							
	Group Number storage for groups attached to this file						
	One byte used per group number if disk contains less						
	255 groups. Two bytes if greater than 256.						
+-----+-----+-----+-----+-----+-----+-----+-----+							
byte 24	byte 25	byte 26	byte 27	byte 28	byte 29	byte 30	byte 31
+-----+-----+-----+-----+-----+-----+-----+-----+							
	Additional Group Number storage.						
	Group Number storage for groups attached to this file						
	One byte used per group number if disk contains less						
	255 groups. Two bytes if greater than 256.						
+-----+-----+-----+-----+-----+-----+-----+-----+							

The bytes of the disk directory entry are each described in the following paragraphs. The first byte stored in an entry is set to indicate if this slot in the predetermined directory area

is empty or if it describes an active file extent. A value of 0E5H indicates an empty slot. This value was chosen presumably due to that a freshly formatted diskette contains all 0E5H bytes in the empty sectors, thus making such disk appear to have no files contained thereon. If the byte value is non 0E5H, then the slot contains a valid file extent descriptor. The CP/M user number area to which an active file is associated is stored in the first directory entry byte. User number values range from 0 to 15.

The next eight bytes contain the primary name of the file in ASCII characters. If the name is shorter than 8 characters then the name is padded to the right with spaces. Following the name field is a three byte file name extension field in ASCII characters. The extension field, if shorter than 3 characters is padded to the right with spaces. For CP/M version 2.2, the upper bits (bit 7) of the extent name bytes are used to describe certain attributes about the file. If the upper bit of the first extent name character is set, then the file is described as a read-only file. The upper bit of the second extent name character, if set, indicates that the file name should not be displayed in directory listings.

Each directory entry, as a file descriptor extent, has the next byte set to a number that specifies which 16K byte chunk of the file that this entry describes. Two bytes after the extent byte are not used within the directory and are normally set to zero by default. The number of records stored in the extent, described by this directory entry, is recorded in the byte 15 position. The maximum value for the record count is 128 (080H) which if equal to  $(128 * 128)$  or 16K bytes, the maximum size of an extent.

Byte positions 16 to 31 contain the group numbers upon the disk that contain the data belonging to the file named in the directory entry. The number of bytes within the total 16 available that are used for group number storage is dependant upon the amount of file data described by this extent and by the group size of the disk. The group numbers are single byte numbers, up to 16 total, if the number of groups upon the disk is less than or equal to 255. If the number of groups upon the disk is more than 255 then byte positions 16 to 31 contain two byte group numbers, stored in low byte/high byte order. The group numbers contained within a directory entry do not have to be in increasing sequential order nor do they have to be consecutive.

The figure below shows two logical records of the directory from a single sided double density disk with 2K byte groups. The total number of groups available is 243 so the group numbers are single byte numbers. Note that only one half of the 16 byte space for group numbers is used due to the fact that 8 entries for 2K

byte groups is all that is needed to describe the storage for one full 16K byte extent.

70	15000000	00000000	00000000	00000000	.....	

The above examples all show files that are less than 16K bytes each. Note also the display showing the erased "USER.LOG" file.

### HOW FILES ARE ACCESSED

The files upon a disk are accessed through a user description block called a File Control Block (FCB for short). The file control block, used by virtually all file access BDOS system calls, has the structure as shown in Figure 3. This chart is taken from a Digital Research CP/M manual and is included here for quick educational reference.

Note that the structure of a file control block is much the same as that of a directory entry with a few minor changes. The changes and/or differences are as follows, otherwise the byte descriptions are the same as for the disk directory entry.

The first byte of an FCB allows the programmer to specify which drive should be used for the file access. Drive A: to P: are specified as 1 to 16 respectively while a value of zero indicates that the currently logged default drive should be used for the access.

An FCB contains four additional bytes that are used as pointers for file access position. The "cr", current record

number, indicates the sequential record number of this extent that will be accessed upon the next file read or file write system call. The user normally sets the "cr" byte to zero to begin file access at the first logical record of the file. Each time a read or write is performed the current record number is incremented. When the "cr" byte attains a value of 080H during a sequential file operation the BDOS automatically realizes that the current extent of the file has been fully accessed and performs the necessary disk directory accesses to setup the FCB to allow file access to the next extent. For reading this simply means that the next extent descriptor directory entry from the disk, for this file, is read into memory (ie. the group allocation numbers from the disk are copied into the d0-dn bytes of the FCB, the extent number becomes one greater, the record count from the disk for the new extent is copied into the "rc" byte and the cr byte is zeroed). During a writing operation the "cr" byte attaining a value of 080H indicates that the current extent of the file is full and so the BDOS automatically finds the appropriate directory entry spot on the disk to write in the newly assigned group allocation bytes, record count value and extent number. The BDOS will then create another directory entry on the disk for the new extent of the file. In this case the d0-dn bytes of the FCB are zeroed to indicate that storage has not yet been allocated for this extent.

Figure 3. FILE CONTROL BLOCK DESCRIPTION

where:

- dr            drive code (0 - 16)
  - 0 => use default drive for file access
  - 1 => select drive A: for file access
  - 2 => select drive B: for file access
  - ...
  - 16=> select drive P: for file access
  
- f1...f8      contain the files name in ASCII upper case with high bits equal to zero.
  
- t1,t2,t3     contain the file type in ASCII upper case with high bits normally equal zero. tn' denotes the high bit of these bit positions.
  - t1' = 1 => Read/Only file
  - t2' = 1 => SYS file, no DIR list
  
- ex           contains the current extent number, normally set to 00 by the user, but is

in the range 0 - 31 during file I/O.

s1 reserved for internal system use

s2 reserved for internal system use, set to zero on call to OPEN, MAKE, SEARCH system calls.

rc record count for extent "ex," takes on values 0 to 128.

d0...dn filled-in by BDOS to indicate file group numbers for this extent.

cr current record to read or write in a sequential file operation. Normally set to zero by the user upon initial access to a file.

r0,r1,r2 optional random record number in the range of 0 to 65535, with overflow to r2. r0/r1 are a 16 bit value in low/high byte order.

The last three bytes of the FCB, r0,r1, & r2 are used for random record file I/O and will be covered in the third and final part of this tutorial. For simpler sequential I/O the FCB in fact does not even need to be setup for the 36 bytes of storage. 33 bytes suffice for all sequential file I/O FCB operations.

## FILE ACCESS SETUP SYSTEM FUNCTIONS

The procedure for the programmer to use in accessing a file generally starts in one of two ways. The first scenario starts with, "Lets see if our file exists on the disk?" There are two BDOS system calls related to the functions of searching the disk directory for a file name match against the FCB specified by the user. These operations allow for the programmer to find out if a specific file name already exists upon the disk. In addition it provides a mechanism to scan a directory to determine all file names that exist in the directory. The second situation comes into being if the programmer is already aware of the file status with respect to "presence" on the disk or as the logical sequence of events following the first scenario. These latter functions are used to work with specific files for opening, closing, creating, renaming and deleting.

## SEARCH FIRST AND SEARCH NEXT: Functions 17 and 18.

The search functions scan the directory for match of a file name that compares with the user specified FCB pointed to by the (DE) register pair. The match is made on the basis of comparing

the f1-f8, t1-t3, and ex bytes of the FCB to the corresponding bytes of the disk directory entries. Any FCB position that contains an ASCII question mark "?" (03FH) is specified as a "match any character" from the disk directory. The function calls return a value of 0FFH in the (A) register if no more matched directory entries can be found. The search functions cause the currently valid disk buffer address and the following 128 bytes to be filled with a copy of the directory record containing the matched entry, if one is found. The (A) register is returned with a 0 to 3 value to indicate which one of the four possible 32 byte chunks of the directory record contain the matched entry.

Search first means to find the first occurrence of a matched entry to the FCB. The search next function scans the directory from the current search position instead of from the beginning. Note that it is not normally valid to perform the search next function without first performing the search first function. Also it is not valid to perform other directory or file operations between the search first and search next functions.

The program example below shows a technique for reading all directory entries from the disk drive specified by the first FCB byte into a memory resident list. The list starts at the LIST label with the total matched file count stored in the FILECNT variable. The LISTPOS label stores the next available list load point during the directory scan operation. The search FCB uses the CP/M default FCB location at address 05CH and specifies a total wild card (\*.\*) match. The "ex" byte is zeroed before the search first call so that only the zero extents of the files are returned. The file names are stored in the list in character strings of 16 bytes each with a preceding drive designator byte and padded to the right with 4 zero bytes. Please note that this program is a segment only and will not directly assemble and run as a CP/M .COM file without a little added lead in and error exit coding.

OPEN FILE: Function 15.

An existing file on a disk may not be read until the user FCB contains the information about where the file is stored upon the diskette. Function 15 provides a means where the user fills in the file name and then calls the operating system to get the d1-dn bytes of the FCB filled in. Once the file is OPEN then it may be read because subsequent calls to the BDOS to READ will "know where" the file is located. The OPEN function returns a value of 0FFH if the file cannot be found, otherwise the (A) register contains a value of 0 to 3 to indicate that the file was successfully opened. To open a file the programming procedure is simply:

```

;
;OPEN FILE EXAMPLE
;
OPEN    EQU    15        ;OPEN FUNCTION CODE
BDOS    EQU    0005H    ;SYSTEM ENTRY

        ORG    0100H    ;START
        LXI    D,FCB    ;POINT AT FILE CONTROL BLOCK
        MVI    C,OPEN    ;FUNCTION
        CALL   BDOS
        CPI    0FFH    ;CHECK IF NOT FOUND
        JZ     ERROR
        RET            ;IF OPEN GO TO CCP
;
ERROR:

```

```

        MVI        C,9          ;PRINT ERROR MESSAGE
        LXI        D,ERRMS
        CALL       BDOS
        RET

;
ERRMS:
        DB         'FILE NOT FOUND','$'
;
;
;FILE ACCESS FILE CONTROL BLOCK
;
FCB:
        DB         00H          ;SET TO USE DEFAULT DRIVE
        DB         'TEST  DAT',0,0,0,0
        DS         16          ;STORAGE FOR D1 TO DN BYTES
        DB         0           ;CURRENT RECORD BYTE
;
        END

```

CLOSE FILE: Function 16.

Whenever a file is accessed for writing new space is allocated for that file on the disk. This implies that the user FCB contains disk group numbers that are not stored upon the diskette in the directory entry for the file. Function 16 provides a means where the user completes the file writing operation and then calls the operating system to set the directory entry group allocation bytes, the rc byte and the extent byte from the corresponding bytes of the FCB. A file that has been opened for reading only need not be closed because there is no change in the stored disk directory information. The CLOSE function returns a value of 0FFH if the file cannot be found, otherwise the (A) register contains a value of 0 to 3 to indicate that the file was successfully closed. To close a file the programming procedure is simply:

```

;
;CLOSE FILE EXAMPLE
;
CLOSE    EQU      16          ;CLOSE FUNCTION CODE
BDOS     EQU      0005H      ;SYSTEM ENTRY

        ORG       0100H      ;START
        LXI       D,FCB      ;POINT AT FILE CONTROL BLOCK
        MVI       C,CLOSE    ;FUNCTION
        CALL      BDOS
        CPI       0FFH       ;CHECK IF NOT FOUND
        JZ        ERROR
        RET          ;IF CLOSED GO TO CCP
;
ERROR:

        DB     00H           ;SET TO USE DEFAULT DRIVE
        DB     'TEST  DAT',0,0,0,0
        DS     16           ;STORAGE FOR D1 TO DN BYTES
        DB     0             ;CURRENT RECORD BYTE
;
        END

```

DELETE FILE: Function 19.

Often time the programmer will create and write files which will subsequently not be needed. The file or files may be deleted through use of function 19. The user sets an FCB to the appropriate file name in the f1-f8, and t1-t3 bytes. The BDOS function then removes the specified file from the directory of the appropriate disk. The user specified file name in the FCB may contain ASCII question marks in which case the delete function may delete multiple files if the file name matches more than one file on the disk with the name. The "?" matches any character at the position of its occurrence in the name. The DELETE function returns a value of 0FFH if the file(s) cannot be found, otherwise the (A) register contains a value of 0 to 3 to indicate that the file was successfully deleted. To delete a file the programming procedure is simply:

```

;
;DELETE FILE EXAMPLE
;
DELETE   EQU     19           ;CLOSE FUNCTION CODE
BDOS     EQU     0005H       ;SYSTEM ENTRY

        ORG     0100H       ;START
        LXI     D,FCB       ;POINT AT FILE CONTROL BLOCK
        MVI     C,DELETE    ;FUNCTION
        CALL    BDOS
        CPI     0FFH        ;CHECK IF NOT FOUND
        JZ      ERROR
        RET                ;IF CLOSED GO TO CCP
;

```

```

ERROR:
    MVI        C,9          ;PRINT ERROR MESSAGE
    LXI        D,ERRMS
    CALL       BDOS
    RET

;
ERRMS:
    DB         'FILE NOT FOUND','$'

;
;
;FILE ACCESS FILE CONTROL BLOCK
;
FCB:
    DB         00H          ;SET TO USE DEFAULT DRIVE
    DB         'TEST  DAT',0,0,0,0
    DS         16          ;STORAGE FOR D1 TO DN BYTES
    DB         0           ;CURRENT RECORD BYTE

;
    END

```

CREATE FILE: Function 22.

Whenever a new file is desired it must first be created so that there is a spot in the directory to later save the file allocation information (see close function above). The BDOS assumes that the programmer has specified a file name that does not exist upon the disk. If there is a chance that a new file is desired that may duplicate the name of one already upon the disk the previously described delete function should be used to erase the old file before creating the new file. Otherwise the directory may contain two files by the same name. The CREATE function returns a value of 0FFH if there is no room in the directory to store the freshly created directory entry, otherwise the (A) register contains a value of 0 to 3 to indicate that the file was successfully created. A newly created file may be immediately written since the BDOS prepares the user FCB to look like an empty file. To create a file the programming procedure is simply:

```

;
;CREATE FILE EXAMPLE
;
CREATE EQU 22          ;CREATE FUNCTION CODE
BDOS EQU 0005H        ;SYSTEM ENTRY

    ORG 0100H        ;START
    LXI D,FCB        ;POINT AT FILE CONTROL BLOCK
    MVI C,CREATE     ;FUNCTION
    CALL BDOS

```

```

        CPI        0FFH        ;CHECK IF DIRECTORY FULL
        JZ         ERROR
        RET                ;IF CLOSED GO TO CCP
;
ERROR:
        MVI        C,9         ;PRINT ERROR MESSAGE
        LXI        D,ERRMS
        CALL       BDOS
        RET
;
ERRMS:
        DB         'DIRECTORY FULL','$'
;
;
;FILE ACCESS FILE CONTROL BLOCK
;
FCB:
        DB         00H        ;SET TO USE DEFAULT DRIVE
        DB         'TEST DAT',0,0,0,0
        DS         16        ;STORAGE FOR D1 TO DN BYTES
        DB         0         ;CURRENT RECORD BYTE
;
        END

```

RENAME FILE: Function 23.

Sometimes it is necessary to change the name of a disk file from that already existing in the disk directory. With function 23 the user specifies the name of an existing file on the disk with a standard FCB format except that on calling the BDOS the d1-dn byte area of the FCB are set to the new name desired for the file. All occurrences of the existing file name (ie. all extents) are changed to match the new name. The drive select byte specifies the drive upon which the rename operation should be done. The first byte of the second 16 bytes of the FCB (d0) is expected to be zero. The RENAME function returns a value of 0FFH if the old name file could not be found, otherwise the (A) register contains a value of 0 to 3 to indicate that the file was successfully renamed. To rename a file the programming procedure is simply:

```

;
;RENAME FILE EXAMPLE
;
RENAME EQU 23        ;RENAME FUNCTION CODE
BDOS   EQU 0005H    ;SYSTEM ENTRY

        ORG        0100H    ;START
        LXI        D,FCB    ;POINT AT FILE CONTROL BLOCK
        MVI        C,RENAME ;FUNCTION

```

```

CALL    BDOS
CPI     0FFH    ;CHECK IF DIRECTORY FULL

DB      'NEWNAME DAT',0,0,0,0 ;NEW NAME
DB      0       ;CURRENT RECORD BYTE
;
END

```

## ACCESSING FILE DATA

The previous section showed the reader how to find and setup files for subsequent I/O. Other file/directory handling functions were also presented. This has all led up to the big moment when the users program is finally ready to read or write data from/to a disk file. So here it is at last...

CP/M disk file data is moved between the disk and memory in blocks of 128 bytes called logical records or "sectors" in older fashioned CP/M lingo. Two functions to be presented here are included in the CP/M BDOS function code to allow sequential access to blocks of data in a file. The READ function starts at the beginning of a file and reads data blocks till the end of the file. The opposing WRITE operation moves data blocks to a new disk file and writes till the end of the users data when the file is closed (or the disk is full if the programmer has too much data). The BDOS includes one other function that allows the user to specify the area in his program where the 128 byte disk record buffer is to be located. These three functions will each be individually described below.

SET DISK BUFFER ADDRESS: Function 26.

The 128 byte data buffer that is to be used by the BDOS for file I/O is based at an address commonly referred to as the "DMA ADDRESS". This address or "buffer pointer" is passed to the BDOS in the (DE) registers when performing function 26. The program below simply sets the buffer address to "DATBF", a storage area after the end of the short program.

```

;
;SET BUFFER ADDRESS EXAMPLE
;
STDMA    EQU    26        ;SET BUFFER ADDRESS FUNCTION CODE
BDOS     EQU    0005H    ;SYSTEM ENTRY

        ORG    0100H    ;START
        LXI   D,DATBF  ;POINT AT DATA BUFFER
        MVI   C,STDMA  ;FUNCTION
        CALL  BDOS
        RET                ;BACK TO CCP
;
DATBF:
        DS    128        ;SETUP 128 BYTE BUFFER
;
        END

```

READ AND WRITE DISK RECORDS: Functions 20 and 21.

The disk read and write functions are very similar in operation in that both move 128 bytes of data to/from the users program. The READ assumes entry with (DE) pointing to an active FCB setup by the open file function. The read sequential function reads the 128 byte record specified by the "cr" field of the FCB into the buffer pointer to by the current disk buffer address. After each READ operation the "cr" field is incremented to the next record number. If the "cr" field overflows past the end of the extent without encountering the end of the file then the BDOS automatically opens the next extent in preparation for the next read operation. The READ function returns a 00H code in the (A) register if the READ was performed successfully. If the end of file is encountered a non zero value is returned in (A).

The WRITE function assumes, on entry to the BDOS, that the (DE) registers point at a validly opened or created FCB. The WRITE will move 128 bytes of data from the buffer specified by the current disk buffer address to the disk. The written record is placed at the "cr" record position of the extent. As each record is written the "cr" field is incremented in preparation for the next write operation. Similar to the READ, if the "cr" field overflows past the end of the current extent, the BDOS automatically closes the current extent and creates a new extent in preparation for the next write operation. The WRITE command

may be performed on an existing file. If the file currently contains data at the "cr" record then the WRITE will overlay the current data with the new 128 byte record. The WRITE function returns a 00H value in the (A) register if the operation is successful. A non-zero value is returned if the write function was unsuccessful due to a full disk or directory.

The small program below is designed to read the first record of a file 'TEST.DAT', and write it into the small file 'ONEREC.DAT'. The program should be reasonably self documenting.

```

## SEQUENTIAL FILE I/O PROGRAMMING EXAMPLE

The assembly language code of Listing 2 presents a comprehensive set of I/O routines that allow either an input or output sequential file to be processed on a byte by byte basis. The routines perform all necessary sector buffering. The reader is encouraged to fully study the code and gain an understanding of how it all works. The program uses most of the BDOS functions

presented in this tutorial.

The reader is invited to be with us again next month when the tutorial continues into its third and final part. The functions of random record file I/O will be presented with complete programming examples to show how random I/O works. Several special file I/O tricks will be shown that permit unique problems to be solved under the CP/M operating system. One of these will be a program that does "update" on an existing file without the use of the random record I/O capabilities. So long till January and I hope that all Life Lines readers have a joyous holiday season.

## PART III

### SLIDING INTO BDOS (Part III)

#### UNDERSTANDING RANDOM FILES

by:

Michael J. Karas  
2468 Hansen Court  
Simi Valley, CA 93065  
(805) 527-7922

The time has arrived to complete the third and final part of

this series on the operation of the CP/M BDOS as viewed from the assembly language programmers perspective. Presently we will build upon the extensive treatment of sequential files presented in Part II of the series to provide a basis for understanding the CP/M 2.2 random file I/O capability. Please note that functions of the BDOS presented here are specific to CP/M Versions 2.2 and 3.0. Older CP/M systems using Version 1.4 do not directly support random access file I/O and as such are not compatible with the programming examples presented below.

#### WHY RANDOM FILE I/O ANYWAY

In the beginning of the CP/M era, sometime around the release of Version 1.3 by Digital Research, small inexpensive single-user micro processor systems were typically used for simple-minded data processing applications. Most computing operations were linear with respect to the data handling by the CPU. Data entered from paper tape, cassette, card readers, or human entry from a keyboard tended to be limited to a sequential processing from start to finish. The usage of such data by the computer in data analysis, program compilation, or logging applications was also largely sequential. Finally the data output operations based upon the needs of hard copy, backup, and transmission from micro to micro were relegated to sequential processing applications.

Anticipated applications of micro type computer hardware by operating system designers, at that time, seemed to dictate that the disk file structures of the operating systems should be sequential in nature. This was true for the earliest releases of CP/M and Intel's ISIS II operating system. Other simple floppy disk operating systems like PERTEC's FDOS and MITS' Disk Extended Basic operating systems were also strictly sequential in the treatment of the disk file allocation and storage. However, these two systems permitted random record I/O within the bounds of an already existing file provided the space to store the records was previously pre-allocated as contiguous disk space in the file structure. The process of random I/O was then easy as a relative offset between the beginning record number for the file and the offset desired within the file.

As the micro processor applications market opened up in the late 1970's it seemed that new uses for computers were being found weekly. It has gotten to the point that micro processor computer users have a large array of very sophisticated software packages to choose from and utilize in their business and hobby activities. The main thing that can be pointed out about many of these packages is that the processes they perform are hardly linear with respect to the handling of data. Interactive programs like word processors, data base managers, spelling checkers, and

spread sheet analysis programs may very well need to be able to store or access data to/from a disk file in a manner that cannot be handled in the old sequential manner. The sequential philosophy generally limited file update to appending to the end of the file and read access to a particular record had to read N-1 records from the beginning of the file prior to being able to read record N.

Random access file I/O within an operating system anticipates the requirements of non-sequential I/O by permitting access to various records directly. Any record that was previously written may be read upon demand. Likewise the user/programmer may write any record desired. The Digital Research CP/M operating system supports this type of I/O in a powerful yet elegantly simple manner through a set of four BDOS system functions. These calls allow random access disk files to be implemented within the standard CP/M compatible file structure.

## RANDOM FILE STRUCTURE UNDER CP/M 2.2

The structure of random files under the CP/M operating system is much the same as that for sequential files. Part II of this series (Lifelines, January 1982) described and illustrated the sequential structure in detail. The reader will recall that CP/M treats disk data in fixed records of 128 bytes. These records are collected together into "groups" that are stored on the disk as an allocated group. The disk space reserved for a given file, in its directory entry, is always marked, identified, and allocated in the even multiples of the "allocation group size".

I previously mentioned two older operating systems that supported random file I/O within the confines of a pre-allocated file. This system requires that all of the space for an "N" record file be reserved as contiguous disk space even if the file only contains two records (#0 and #N). Making a random access file bigger than the pre allocated size was virtually impossible. The CP/M Ver 2.2 random file access system has overcome the problems described above. A random file under CP/M contains only the number of allocated groups required to hold the stored records. The holes between the defined records do not consume unused disk space.

If a file under CP/M is created with only random record 0 of the file written then that file contains 128 bytes of real data and consumes one allocation group of disk space. The allocation group consumed also may contain other adjacent random records to fill out the size of the group. For instance, on single density 8" disks with a 1024 byte allocation group size, a one record (#0) file would be able to be written with additional record

numbers 1 to 7 within the same allocation group. Likewise if a single record file was created with only record number 9 written, that file would consume only one allocation group of disk space. Additional record numbers 8, and 10 to 15 could then be written without requiring additional disk space.

### RANDOM FILE I/O SYSTEM CALLS

Let us next investigate the five BDOS system calls that CP/M supports for random I/O within files. The chart of Figure 1 on the following page details the look of a random access file control block. Note that the file control block contains three bytes at the end that are used to store the random record number that will currently be accessed. The random access system calls all utilize this field to determine the portion of the file to access at read/write time.

A CP/M random file may contain up to 64K records of 128 bytes numbered from 0 to 65535. Two bytes of the file control block hold this record number, r0 as the low byte and r1 as the high byte. This provides accessibility to records up to a maximum file size of 8 megabytes. The r2 byte of the file control block is not used except as the overflow or carry out of the r1 byte. If byte r2 ever contains a value that is non-zero the record number is beyond the end of the 8 megabyte limit for the file.

To access a random file, it must first be opened in the normal manner with the "open" BDOS function call. In the case of creating a new random file the make file BDOS call is sufficient in that the the results of the make operation are equivalent to the open function on a zero length file.

### READ RANDOM RECORD: Function 33.

This system call is made with the (DE) register pair pointing to a 36 byte file control block. Bytes r0-r2 are set up with the random record to read. The BDOS then fetches the addressed record from the file and places it in the callers record buffer pointed to by the last set buffer address function

Figure 1. FILE CONTROL BLOCK DESCRIPTION

where:

dr            drive code (0 - 16)  
              0 => use default drive for file access  
              1 => select drive A: for file access  
              2 => select drive B: for file access  
              ...  
              16=> select drive P: for file access

f1...f8      contain the files name in ASCII upper case  
              with high bits equal to zero.

t1,t2,t3     contain the file type in ASCII upper case  
              with high bits normally equal zero. tn' denotes  
              the high bit of these bit positions.  
              t1' = 1 => Read/Only file  
              t2' = 1 => SYS file, no DIR list

ex            contains the current extent number,  
              normally set to 00 by the user, but is  
              in the range 0 - 31 during file I/O.

s1            reserved for internal system use

s2            reserved for internal system use, set to  
              zero on call to OPEN, MAKE, SEARCH system  
              calls.

rc            record count for extent "ex," takes on values  
              0 to 128.

d0...dn      filled in by BDOS to indicate file group numbers  
              for this extent.

cr            current record to read or write in a sequential  
              file operation. Normally set to zero by the user  
              upon initial access to a file.

r0,r1,r2     optional random record number in the range of 0 to  
              65535, with overflow to r2. r0/r1 are a 16 bit value  
              in low/high byte order.

call. The r0-r2 fields of the file control block are not changed as a result of the random read function such that a subsequent random read operation would read the same record. The random read function may return a number of error codes as described below:

Error Code 00 - The random read function worked without error and the user buffer contains the desired data.

Error Code 01 - The random read operation addresses a record that is contained in a disk allocation group not allocated to the file. This means that the group field number slot of the appropriate extent of the file that

should contain the record is equal to 0.

Error Code 03 - The random read operation just requested required that a different extent descriptor directory entry had to be open for the impending operation, however prior to opening the new extent the current extent could not be closed due to disk read/only status or a disk change.

Error Code 04 - The random read operation just requested required access to an extent of the file that does not exist on the disk.

Error Code 06 - The random read operation just requested required access to a record number beyond the bounds of the disk drive, ie the disk drive is less than 8 megabytes and the record requested is within an allocation group beyond the end of the disk.

#### WRITE RANDOM RECORD: Function 34.

This system call is made with the (DE) register pair pointing to a 36 byte file control block. Bytes r0-r2 are set up with the random record to write. The BDOS then moves the data in the callers record buffer pointed to by the last set buffer address function call to the addressed record in the file. The r0-r2 fields of the file control block are not changed as a result of the random write function such that a subsequent random write operation would write the same record. The random write function may return a number of error codes as described below:

Error Code 00 - The random write function worked without error and the user buffer contains the desired data.

Error Code 03 - The random write operation just requested required that a different extent descriptor directory entry had to be open for the impending operation, however prior to opening the new extent the current extent could not be closed due to disk read/only status or a disk change.

Error Code 05 - The random write operation just requested required access to an extent of the file that does not exist on the disk. In the process of creating the new extent the disk directory was found to be full.

Error Code 06 - The random write operation just requested required access to a record number beyond the bounds of

the disk drive, ie the disk drive is less than 8 megabytes and the record requested is within an allocation group beyond the end of the disk.

#### WRITE RANDOM RECORD WITH ZERO FILL: Function 40.

This system call is made with the (DE) register pair pointing to a 36 byte file control block. Bytes r0-r2 are set up with the random record to write. The BDOS then moves the data in the callers record buffer, pointed to by the last set buffer address function call, to the addressed record in the file. The r0-r2 fields of the file control block are not changed as a result of the random write function such that a subsequent random file operation would access the same record. If the random write operation caused a new allocation group to be allocated to the file the other records of the same block are filled with zeros. The random write with zero fill function may return a number of error codes identical to those described for function number 34 above.

#### COMPUTE FILE SIZE: Function 35.

This system call determines the number of 128 byte records in a file and sets the number of records into the r0 and r1 bytes of the 36 byte file control block addressed by the (DE) register pair. The returned size is a virtual size in that if the file was created by random write operations and the file contains "holes" the file size function does not take the holes into account. Another way of looking at this is to think of this function as returning a record number that is one greater than the maximum record number currently in the file. If the file had no "holes" or it had been written in the conventional sequential fashion, then the file size reported by this function is the real file size. This function provides a convenient function of positioning a file at its end so that subsequent sequential or random update could be performed.

#### SET RANDOM RECORD: Function 36:

The (DE) register pair is set to point to a 36 byte file control block that has previously been used to reference a file in the sequential mode. Upon reference with this system call the r0 to r2 fields are filled in with the random record number that corresponds to the current file position, ie the BDOS simply computes the real current record number as follows:

The current extent number is multiplied by 128, the number of records per extent, and to this product is added the numerical value of the CR field, current record in this extent. The final result is placed into the r0-r2 fields of the FCB.

## LOOKING AT SOME EXAMPLES

The following simple assembly language program is designed to write record numbers 0 and 143 into a file on the disk. The write random function is used to write the first record with all A's and the second record, # 143, with all B's.

The above program was assembled and caused to run on an empty single density disk in the default disk drive. The following display shows how the directory upon the disk looked after running the program. Notice that the file only consumes two allocated groups. Due to the fact that this was a single density disk with 1024 byte allocation groups of 8 records each, then if record number 8 was subsequently written the directory entries would change to include an allocation block number in the second group number slot of the first extent of the file.

```

the first demonstration program was changed to cause the second write operation to be done with zero fill. The changed portion of the program is shown below:

```

LXI  D,RANDFCB    ;WRITE RECORD OF A'S
MVI  C,WRAND      ;NORMAL WRITE RANDOM FUNCTION
CALL  BDOS
;
MVI  A,'B'        ;FILL NEXT RECORD WITH B'S
CALL  FILL        ;GO FILL
LXI  H,143        ;SET RECORD NUMBER TO WRITE B'S INTO
SHLD  RR
LXI  D,RANDFCB    ;WRITE RECORD OF B'S
MVI  C,WRANDF     ;WRITE RANDOM ZERO FILL FUNCTION
CALL  BDOS
;
LXI  D,RANDFCB    ;CLOSE JUST WRITTEN FILE

```

Note from the directory display below that there is no change in the appearance of the entries from the first example.

This time the only thing that changed was the data in allocation group 3. Due to the second write this allocation group contains a sector of B's at GROUP=03:07 with the other seven sectors of the group now containing zeroes from the zero fill operation. The function of zero fill is to leave a clean slate on records numbers subsequently read from the same allocation block. The BDOS is capable of reporting unwritten record information for records that correspond to group number slots in the directory entries that contain a '00' byte indicating unallocated. However once a group is allocated for one record the BDOS cannot determine if other sectors of that group have been written or not. Thus ero function may be issued when creating a random access file for the first time. The programmer may then use a record of 128 zeroes to indicate that the record is not used as opposed to accidentally mistaking the garbage data from uninitialized sectors written without zero fill as real data.

```

The next example program is included here to show a clever means of implementing arbitrary record selection I/O within a file without resorting to random file I/O. The intent is not to indicate that the following scheme is the preferred method. The program below was developed with the CP/M Ver 1.4 operating system in mind. However the algorithm works fine with CP/M 2.2 as well. The technique used to play with random records by using sequential read and write operations is to manipulate the "cr" field of a standard 33 byte file control block. The "cr" byte is the only meand that the BDOS uses to indicate the next record to access. The programmer may change this byte value to force the BDOS to go to any record within the current extent.

If the first extent of a file is opened, the group allocation values for that extent lie in the file control block. If the technique of performing "your own" random I/O is done, the code must access record numbers not to excede 07fh without first closing the current extent and opening the next. This can be done with either the conventional open and close operations or the programmer, when done working with the current extent may open next automatically by performing a dummy read of record 080H of

the current extent. The programming example below uses the "roll your own" technique but does not anticipate a file size greater than 16K (one extent size).

The program below is a skeleton structure of a .COM file serialization procedure. The idea is to insert a six byte serial number string into the target file PROG.COM on drive B:. The serial number is inserted into the file at the places specified by the labels in the table at the start of the listing. These values are stripped out of the symbol table that is generated at the assembly of the PROG.ASM file. If the assembler does not generate a symbol table then the label values may be pulled off the .PRN listing output. The insert points are places within the "to be serialized" program where the programmer has determined that he would like to place the serial number string. Within the file itself, the labels point to the place where the string is to be inserted with respect to run time load address. The real file offset is 0100H bytes less. In addition, the scheme does not insert all six bytes of the program serial number at each location. The byte at each label address minus one contains a value between 1 and 6 of the number of serial number bytes that should actually be inserted at seralization time.

The list of label values in the program below is used to build, at assembly time, a table of record numbers where the specific serial number strings are to be inserted. This table is then used to fill in the "cr" byte of the file control block as each serial number is to be inserted. The table also contains the byte offset within the record where the insert point is to start. As each serial number is to be inserted the appropriate record is read, the number is inserted (with length specified by the value from the file record just accessed), and the record is written back to the disk. Sequential read and write operations are used for both operations. Logic within the code listing below also provides for the occurrence that the serial number string may cross the end of the first record and flow into the next record. In this case the first is rewritten followed by reading of the next with the remainder of the insert proceeding from the beginning of the second record.

Please note that the program example is given as a skeleton only and the serial number entry process, increment process, and the disk I/O error exit points are left for the reader/programmer to fill in with code of his own choosing.

The next and final example is a fully functional program that uses random record I/O under CP/M 2.2 to perform a "useful" function. The program mixes up the records of a file in an ordered yet bizarre way in order that the file contents may be encoded to prevent its use until such time that it is unscrambled. The unmixing process is also performed by the program below. The records or "sectors" of the file are mixed and unmixed in place on the disk in that the disk file is not copied. Random access file I/O is used to swap records directly. The comment block at the beginning of the program listing contains an explanation of the program "intent" and the record mixing algorithm chosen. Operation of the program, should the reader wish to utilize the encoding and decoding functions provided, is also described in the listing.

This example program is presented as a working example of random file I/O in use. Detailed description of the internal workings of the program are beyond the scope of this tutorial but may be inferred by studying the listing and reading the rather

prolific comment statements. For readers that would like to avoid the aggravation of typing in the source code for the program below or for the other programs presented in this BDOS tutorial series, Part I in Lifelines, November 1982 and Part II in Lifelines, January 1983, a machine readable copy of the source code files on an eight inch single density diskette may be obtained from Michael J. Karas, 2468 Hansen Court, Simi Valley, California 93065. Please send diskettes preformatted, labeled and in a returnable mailer of some sort. Also include either stamps or money for return postage (no postage meter tapes, those are accepted on date of printing only) for your return package.

LISTING FOR SECRET.ASM A RANDOM I/O PROGRAM EXAMPLE

```
;
;
;RANDOM RECORD I/O DEMONSTRATION FOR CP/M 2.2
;
; THIS THIRD LEVEL DEMONSTRATION PROGRAM IS DESIGNED TO
; DEMONSTRATE RANDOM FILES BY DEVELOPING A 'NOT NECESSARILY
; PRACTICAL' ALGORITHM FOR ENCODING A PROGRAM FILE ON A DISK.
; THE INTENT IS TO MAKE THE TRANSMISSION OF AN OBJECT FILE
; ARBITRARILY SCRAMBLED ON A 128 BYTE BY 128 BYTE RECORD BASIS
; SUCH THAT IF THE TRANSMITTED FILE, EITHER ON FLOPPY DISKETTE
; OR ON THE PHONE LINE WERE INTERCEPTED BY AN ILLICIT THIRD
; PARTY, THEN THE THIRD PARTY WOULD RECEIVE GARBAGE UNLESS
; HE HAD POSSESSION OF THE DECODING ALGORITHM.
;
; THIS PROGRAM WILL IMPLEMENT SUCH AN ALGORITHM IN BOTH AN
; ENCODING AND DECODING FORMAT. HERE IS THE ALGORITHM USED.
; (OBVIOUSLY DUE TO THE FACT THAT THIS APPEARS IN THE
; PUBLIC IMAGE AS A MAGAZINE ARTICLE WILL PREVENT THE FOLLOWING
; ALGORITHM TO BE OF 'SECRET' USE).
;
; THE OPERATOR ENTERS THE COMMAND TO RUN THE PROGRAM AS:
;
;     A>SECRET filename.typ E<cr>
;
;         where filename.typ is the
;         file to encode. And "E"
;         indicates to encode the file
;
; or:
;
;     A>SECRET filename.typ D<cr>
;
;         where filename.typ is the
;         file to decode. And "D"
;         indicates to decode the file
;
; THE ENCODING PROCESS WRITES THE ENCODED FILE RIGHT IN PLACE
```

```
; WITHIN THE USER SPECIFIED FILE. NO MEANS IS USED TO SPECIFY
; IN THE ENCODED FILE THAT IT IS ENCODED.
;
; THE DECODE PROCESS READS AND DECODES THE FILE RIGHT IN PLACE
; WITHIN THE USER SPECIFIED FILE NAME.
;
; THE ALGORITHM LEAVES THE FIRST RECORD OF THE FILE INTACT AND
; DOES NOT ENCODE THE PART OF A FILE BEYOND 128 RECORDS IN SIZE.
; FOR FILES LARGER THAN 128 RECORDS THE FINAL RECORDS BEYOND THE
; 128'TH ARE LEFT UNTOUCHED. THE BDOS IS CALLED TO DETERMINE THE
; SIZE OF THE FILE SO THE NUMBER OF RECORDS IN THE FILE ARE
; KNOWN. THIS NUMBER OF RECORDS WILL BE REFERRED TO HERE AS "NR".
; IF "NR" IS GREATER THAN 128 THEN "NR" IS SET TO 128. THEN THE
; FIRST "NR-1" BYTES OF THE FIRST RECORD ARE READ SEQUENTIALLY
; TO MAKE A LIST OF ONE BYTE BINARY NUMBERS WITH A NUMBER OF
; ENTRIES EQUAL TO THE NUMBER OF RECORDS IN THE FILE MINUS ONE,
; UP TO A MAXIMUM OF 127 NUMBERS.
;
; THIS LIST IS THEN PROCESSED TO CONVERT ALL OF THE NUMBERS IN THE
; LIST TO BE WITHIN THE RANGE OF 1 TO "NR-1". THIS CONVERSION IS
; DONE BY FIRST "ANDING" EACH OF THE BYTES IN THE LIST WITH A MASK.
; THE MASK HAS A NUMERICAL VALUE EQUAL TO "NR-1" ROUNDED UP TO
; THE NEXT BIGGEST [(2 ^ N) - 1] VALUE, IE IF THE FILE HAS 5
; RECORDS THE MASK IS 07H. IF THE FILE HAS 59 RECORDS THE MASK
; HAS A VALUE OF 3FH. THE LIST IS THEN SCANNED FOR VALUES THAT
; ARE GREATER THAN "NR-2". EACH VALUE THAT IS GREATER THAN
; "NR-2" IS DIVIDED BY TWO IGNORING THE REMAINDER. FINALLY EACH
; LIST VALUE IS INCREMENTED BY ONE TO MAKE A REAL FILE READABLE
; RECORD NUMBER.
;
; THE LIST IS THEN USED AS A RECORD SCRAMBLE/UNSCRAMBLE LIST.
; FOR SCRAMBLING IT IS SCANNED FROM THE BEGINNING WHILE
; UNSCRAMBLING SCANS THE LIST FROM THE END. SCRAMBLING PROCEEDS
; AS FOLLOWS (THE UNSCRAMBLE PROCESS IS THE REVERSE):
;
; THE SECOND FILE RECORD IS NOW INTERCHANGED IN
; POSITION WITH THE RECORD POINTED BY THE FIRST
; NUMBER IN THE LIST. THE THIRD FILE RECORD IS
; INTERCHANGED WITH THE RECORD POINTED TO BY THE
; SECOND LIST VALUE. THIS PROCESS CONTINUES UNTIL
; THE END OF THE LIST. DURING THE PROCESS OF
; INTERCHANGING THE FILE SECTORS IN THIS RATHER
; BIZARRE MANNER, EACH TIME A LIST VALUE IS FOUND
; TO HAVE A LEAST SIGNIFICANT BIT THAT IS EQUAL
; TO "1" THEN THAT RECORD HAS EACH BYTE XOR'ED
; WITH THE RECORD NUMBER.
;
